done
```

troubleshoot.txt

75 lines

```
General:
Write down most of your thoughts, even if you're not sure
whether they're useful.
Give your variables (and files) meaningful names.
Stay organized and don't leave papers all over the place!
You should know what your code is doing ...

Pre-submit:
Write a few simple test cases if sample is not enough.
Are time limits close? If so, generate max cases.
Is the memory usage fine?
Could anything overflow?
Remove debug output.
Make sure to submit the right file.
```

Wrong answer:
Print your solution! Print debug output as well.
Read the full problem statement again.
Have you understood the problem correctly?
Are you sure your algorithm works?
Try writing a slow (but correct) solution.
Can your algorithm handle the whole range of input?
Did you consider corner cases (ex. n=1)?
Is your output format correct? (including whitespace)
Are you clearing all data structures between test cases?
Any uninitialized variables?
Any undefined behavior (array out of bounds)?
Any overflows or NaNs (or shifting ll by >=64 bits)?
Confusing N and M, i and j, etc.?
Confusing ++i and i++?
Return vs continue vs break?
Are you sure the STL functions you use work as you think?
Add some assertions, maybe resubmit.
Create some test cases to run your algorithm on.
Go through the algorithm for a simple case.
Go through this list again.
Explain your algorithm to a teammate.
Ask the teammate to look at your code.
Go for a small walk, e.g. to the toilet.
Rewrite your solution from the start or let a teammate do it.

Geometry:
Work with ints if possible.
Correctly account for numbers close to (but not) zero. Related:
for functions like acos make sure absolute val of input is not
(slightly) greater than one.
Correctly deal with vertices that are collinear, concyclic,
coplanar (in 3D), etc.
Subtracting a point from every other (but not itself)?

Runtime error:
Have you tested all corner cases locally?
Any uninitialized variables?
Are you reading or writing outside the range of any vector?
Any assertions that might fail?
Any possible division by 0? (mod 0 for example)
Any possible infinite recursion?
Invalidated pointers or iterators?
Are you using too much memory?
Debug with resubmits (e.g. remapped signals, see Various).

Time limit exceeded:
Do you have any possible infinite loops?
What's your complexity? Large TL does not mean that something
simple (like NlogN) isn't intended.
Are you copying a lot of unnecessary data? (References)
Avoid vector, map. (use arrays/unordered_map)
How big is the input and output? (consider FastIO)
What do your teammates think about your algorithm?
Calling count() on multiset?

Memory limit exceeded:
What is the max amount of memory your algorithm should need?
Are you clearing all data structures between test cases?
If using pointers try BumpAllocator.

Mathematics (2)

2.1 Trigonometry

$$\sin(v+w) = \sin v \cos w + \cos v \sin w$$

$$\cos(v+w) = \cos v \cos w - \sin v \sin w$$

$$\tan(v+w) = \frac{\tan v + \tan w}{1 - \tan v \tan w}$$

$$\sin v + \sin w = 2 \sin \frac{v+w}{2} \cos \frac{v-w}{2}$$

$$\cos v + \cos w = 2 \cos \frac{v+w}{2} \cos \frac{v-w}{2}$$

$$a \cos x + b \sin x = r \cos(x - \phi)$$

$$a \sin x + b \cos x = r \sin(x + \phi)$$

where $r = \sqrt{a^2 + b^2}$, $\phi = \operatorname{atan2}(b, a)$.

2.2 Geometry

2.2.1 Triangles

Side lengths: a, b, c

Semiperimeter: $s = \frac{a+b+c}{2}$

Area: $A = \sqrt{s(s-a)(s-b)(s-c)}$

Circumradius: $R = \frac{abc}{4A}$

Inradius: $r = \frac{A}{p}$

Length of median (divides triangle into two equal-area triangles):

$$m_a = \frac{1}{2} \sqrt{2b^2 + 2c^2 - a^2}$$

Length of bisector (divides angles in two):

$$s_a = \sqrt{bc \left[1 - \left(\frac{a}{b+c} \right)^2 \right]}$$

Law of sines: $\frac{\sin \alpha}{a} = \frac{\sin \beta}{b} = \frac{\sin \gamma}{c} = \frac{1}{2R}$

Law of cosines: $a^2 = b^2 + c^2 - 2bc \cos \alpha$

Law of tangents: $\frac{a+b}{a-b} = \frac{\tan \frac{\alpha+\beta}{2}}{\tan \frac{\alpha-\beta}{2}}$

2.3 Derivatives/Integrals

$$\frac{d}{dx} \arcsin x = \frac{1}{\sqrt{1-x^2}} \qquad \frac{d}{dx} \arccos x = -\frac{1}{\sqrt{1-x^2}}$$

$$\frac{d}{dx} \tan x = 1 + \tan^2 x \qquad \frac{d}{dx} \arctan x = \frac{1}{1+x^2}$$

$$\int \tan ax = -\frac{\ln |\cos ax|}{a} \qquad \int x \sin ax = \frac{\sin ax - ax \cos ax}{a^2}$$

$$\int e^{-x^2} = \frac{\sqrt{\pi}}{2} \operatorname{erf}(x) \qquad \int x e^{ax} dx = \frac{e^{ax}}{a^2} (ax - 1)$$

Integration by parts:

$$\int_a^b f(x)g(x)dx = [F(x)g(x)]_a^b - \int_a^b F(x)g'(x)dx$$

2.4 Sums/Series

2.4.1 Progressions

Arithmetic (first term a , diff d): $S_n = \frac{n}{2}(2a + (n - 1)d)$

Geometric (first term a , ratio $r \neq 1$): $S_n = a\frac{r^n-1}{r-1}$

Infinite GP ($|r| < 1$): $S_\infty = \frac{a}{1-r}$

Arithmetico-Geometric $(a, (a + d)r, (a + 2d)r^2 \dots, |r| < 1)$:

$$S_\infty = \frac{a}{1-r} + \frac{dr}{(1-r)^2}$$

2.4.2 Finite Sums

$$1 + 2 + 3 + \cdots + n = \frac{n(n + 1)}{2}$$
$$1^2 + 2^2 + 3^2 + \cdots + n^2 = \frac{n(n + 1)(2n + 1)}{6}$$
$$1^3 + 2^3 + 3^3 + \cdots + n^3 = \frac{n^2(n + 1)^2}{4}$$
$$1^4 + 2^4 + 3^4 + \cdots + n^4 = \frac{n(n + 1)(2n + 1)(3n^2 + 3n - 1)}{30}$$
$$1 + 3 + 5 + \cdots + 2n - 1 = n^2$$
$$2 + 4 + 6 + \cdots + 2n = n(n + 1)$$

2.4.3 Taylor Series

$$\ln(1 + x) = x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \dots, (-1 < x \leq 1)$$
$$\sqrt{1 + x} = 1 + \frac{x}{2} - \frac{x^2}{8} + \frac{2x^3}{32} - \frac{5x^4}{128} + \dots, (-1 \leq x \leq 1)$$
$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \dots, (-\infty < x < \infty)$$
$$\cos x = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \dots, (-\infty < x < \infty)$$

2.5 Probability theory

Let X be a discrete random variable with probability $p_X(x)$ of assuming the value x . It will then have an expected value (mean) $\mu = \mathbb{E}(X) = \sum_x xp_X(x)$ and variance $\sigma^2 = V(X) = \mathbb{E}(X^2) - (\mathbb{E}(X))^2 = \sum_x (x - \mathbb{E}(X))^2p_X(x)$ where σ is the standard deviation.

$$\mathbb{E}(aX + bY) = a\mathbb{E}(X) + b\mathbb{E}(Y)$$

If X, Y are independent,

$$V(aX + bY) = a^2V(X) + b^2V(Y).$$

Expectation is linear If X is instead continuous it will have a probability density function $f_X(x)$ and the sums above will instead be integrals with $p_X(x)$ replaced by $f_X(x)$.

Data Structures (3)

3.1 STL

MapComparator.h

Description: example of function object (functor) for map or set

Usage: set<int,cmp> s; map<int,int,cmp> m; 5bfa6c, 1 lines

```
struct cmp{bool operator() (int l,int r){return l>r;}};
```

HashMap.h

Description: Hash map with similar API as unordered_map. Initial capacity must be a power of 2 if provided.

Usage: gp_hash_table<int, int, chash> h({},{},{},{},{1<<16});

Memory: ~1.5x unordered map

Time: ~3x faster than unordered map

<ext/pb_ds/assoc.container.hpp> e58314, 12 lines

```
using namespace __gnu_pbds;
struct chash {
    const uint64_t C = 4e18*acos(0)+71;
    const int R = chrono::steady_clock::now().time_since_epoch().
        ↪count();
    size_t operator() (uint64_t x) const {
        return __builtin_bswap64((x^R)*C);
    }
};
template <class K, class V> using HT = gp_hash_table<K, V,
    ↪chash>;
template <class K, class V> V get(HT<K, V> &u, K x) {
    auto it = u.find(x); return it == u.end() ? 0 : it->second;
}
```

OrderStatisticTree.h

Description: A set (not multiset!) with support for finding the n 'th element, and finding the index of an element. Change null_type to get a map.

Time: $\mathcal{O}(\log N)$

<ext/pb_ds/assoc.container.hpp> 222518, 18 lines

```
using namespace __gnu_pbds;
template<class T> using IndexedSet = tree<T, null_type,
less<T>, rb_tree_tag, tree_order_statistics_node_update>;

#define ook order_of_key // position of the given element
#define fbo find_by_order // return an iterator

// Number of element <= k
int atMost(IndexedSet<pair<int, int>>& T, int k) {
    return T.order_of_key({k, INT_MAX});
}
// Number of element grater >= k
int atLeast(IndexedSet<pair<int, int>>& T, int k) {
    return T.size() - T.order_of_key({k, INT_MIN});
}
int getSum(IndexedSet<pair<int, int>>& T, int l, int r) {
    return atMost(T,r)-atMost(T,l-1);
}
```

SWAG.h

Description: SWAG (Sliding Window Aggregation) using two stacks. Supports queue operations with O(1) amortized aggregate queries. Works for any associative operation (OR, AND, XOR, GCD, MIN, MAX, SUM, etc).

Usage: Queue<int> q;

q.push(x);

q.pop();

q.query(); // aggregate over all elements in queue

Memory: $\mathcal{O}(n)$

Time: push $\mathcal{O}(1)$, pop $\mathcal{O}(1)$ amortized, query $\mathcal{O}(1)$ 5aa600, 29 lines

```
template<class T> struct Stack {
    vector<pair<T, T>> stk;
    T cmb(T x) {
        return stk.empty() ? x : min(stk.back().second, x);
    }
    void push(T x) { stk.push_back({x, cmb(x)}); }
    void pop() { stk.pop_back(); }
    T agg() const { return stk.back().second; }
};
```

```
template<class T> struct Queue {
    Stack<T> in, out;
    T cmb(T a, T b) {
        return min(a, b);
    }
    void push(T x) { in.push(x); }
    void pop() {
        if (out.stk.empty()) while (!in.stk.empty()) {
            out.push(in.stk.back().first);
            in.pop();
        }
        out.pop();
    }
    T query() {
        if (in.stk.empty()) return out.agg();
        if (out.stk.empty()) return in.agg();
        return cmb(in.agg(), out.agg());
    }
};
```

3.2 1D Range Queries

RMQ.h

Description: 1D range minimum query. If TL is an issue, use arrays instead of vectors and store values instead of indices.

Memory: $\mathcal{O}(N \log N)$

Time: $\mathcal{O}(1)$

a3f881, 19 lines

```
tcT> struct RMQ { // floor(log_2(x))
    int level(int x) { return 31-__builtin_clz(x); }
    V<T> v; V<vi> jmp;
    int cmb(int a, int b) {
        return v[a]==v[b]?min(a,b):(v[a]<v[b]?a:b); }
    void init(const V<T>& _v) {
        v = _v; jmp = {vi(sz(v))};
        iota(all(jmp[0]),0);
        for (int j = 1; 1<<j <= sz(v); ++j) {
            jmp.pb(vi(sz(v)-(1<<j)+1));
            F0R(i,sz(jmp[j])) jmp[j][i] = cmb(jmp[j-1][i],
                jmp[j-1][i+(1<<(j-1))]);
        }
    }
    int index(int l, int r) {
        assert(l <= r); int d = level(r-l+1);
        return cmb(jmp[d][l],jmp[d][r-(1<<d)+1]); }
    T query(int l, int r) { return v[index(l,r)]; }
};
```

BIT.h

Description: Computes partial sums $a[0] + a[1] + \dots + a[\text{pos} - 1]$, and updates single elements $a[i]$, taking the difference between the old and new value. 0-Indexed.

Time: Both operations are $\mathcal{O}(\log N)$.

29f859, 26 lines

```
template<class T> struct BIT {
    int N; vector<T> bit;
    BIT(int _N) {
        N = _N;
        bit.resize(N);
    }
    void add(int p, T x) {
        for (++p; p <= N; p += p&-p) bit[p - 1] += x;
    }
    T sum(int l, int r) { return sum(r+1)-sum(l); }
    T sum(int r) {
        T res = 0;
        for (; r; r -= r&-r) res += bit[r - 1];
        return res;
    }
    int lower_bound(T sum) {
        if (sum <= 0) return -1;
        int pos = 0;
        for (int pw = 1 << 25; pw; pw >= 1) {
            int npos = pos + pw;
            if (npos <= N && bit[npos - 1] < sum)
                pos = npos, sum -= bit[pos - 1];
        }
        return pos;
    }
};
```

SegmentTree.h
Description: 1D point update and range query where cmb is any associative operation. seg[1]==query(0,N-1).
Time: $\mathcal{O}(\log N)$

a09d9c, 36 lines

```
template<class T> struct SegmentTree {
    const T ID{};
    T cmb(T a, T b) { return a + b; }
    int N = 1; vector<T> seg;
    SegmentTree(int _N) {

    return a*sum2(n)+b*n-m*divSum(n,a,b,m); }
```

4.2 Primality

4.2.1 Primes

$p = 962592769$ is such that $2^{21} \mid p - 1$, which may be useful. For hashing use 970592641 (31-bit number), 31443539979727 (45-bit), 3006703054056749 (52-bit). There are 78498 primes less than 1 000 000.

Primitive roots exist modulo any prime power p^a , except for $p = 2, a > 2$, and there are $\phi(\phi(p^a))$ many. For $p = 2, a > 2$, the group $\mathbb{Z}_{2^a}^\times$ is instead isomorphic to $\mathbb{Z}_2 \times \mathbb{Z}_{2^{a-2}}$.

4.2.2 Divisors

$\sum_{d|n} d = O(n \log \log n)$.

The number of divisors of n is at most around 100 for $n < 5e4$, 500 for $n < 1e7$, 2000 for $n < 1e10$, 200 000 for $n < 1e19$.

Let $n = \prod_i p_i^{e_i}$ be the prime factorization of n .

Number of Divisors: $d(n) = \prod_i (e_i + 1)$.

Sum of Divisors: $\sigma(n) = \prod_i \frac{p_i^{e_i+1}-1}{p_i-1}$.

Product of Divisors:

Case 1: n is a perfect square. Then $\prod_{d|n} d = \sqrt{n}^{d(n)}$.

Case 2: n is not a perfect square. Then $\prod_{d|n} d = n^{d(n)/2}$.

Euler's Totient Function:
 $\phi(n) = n \prod_i (1 - \frac{1}{p_i}) = \prod_i (p_i^{a_i} - p_i^{a_i-1})$.

Dirichlet Convolution: Given a function $f(x)$, let

$(f * g)(x) = \sum_{d|x} g(d)f(x/d)$.

If the partial sums $s_{f*g}(n), s_g(n)$ can be computed in $O(1)$ and $s_f(1 \dots n^{2/3})$ can be computed in $O\left(n^{2/3}\right)$ then all $s_f\left(\frac{n}{d}\right)$ can as well. Use

$$s_{f*g}(n) = \sum_{d=1}^n g(d)s_f(n/d).$$

If $f(x) = \mu(x)$ then $g(x) = 1, (f * g)(x) = (x == 1)$, and $s_f(n) = 1 - \sum_{i=2}^n s_f(n/i)$.

If $f(x) = \phi(x)$ then $g(x) = 1, (f * g)(x) = x$, and $s_f(n) = \frac{n(n+1)}{2} - \sum_{i=2}^n s_f(n/i)$.

Let $s(x) = \sum_{i=1}^x \phi(i)$. Then

$$s(n) = \frac{n(n+1)}{2} - \sum_{i=2}^n s\left(\left\lfloor \frac{n}{i} \right\rfloor\right)$$

can be computed in faster than $\Theta(n)$.

FactorBasic.h

```

4.3 Euclidean Algorithm

4.3.1 Bézout’s identity

For $a \neq b \neq 0$, then $d = \gcd(a, b)$ is the smallest positive integer for which there are integer solutions to

$$ax + by = d$$

If (x, y) is one solution, then all solutions are given by

$$\left(x + \frac{kb}{\gcd(a,b)}, y - \frac{ka}{\gcd(a,b)}\right), \quad k \in \mathbb{Z}$$

FracInterval.h

Description: Given fractions $a < b$ with non-negative numerators and denominators, finds fraction f with lowest denominator such that $a < f < b$. Should work with all numbers less than 2^{62} .

```
1860f3, 6 lines

pl bet(pl a, pl b) {
    ll num = a.f/a.s; a.f -= num*a.s, b.f -= num*b.s;
    if (b.f > b.s) return {1+num,1};
    auto x = bet({b.s,b.f},{a.s,a.f});
    return {x.s+num*x.f,x.f};
}
```

Euclid.h

Description: Generalized Euclidean algorithm. euclid and invGeneral work for $A, B < 2^{62}$.

Time: $\mathcal{O}(\log AB)$

```
83ab06, 13 lines

// For A,B>=0, finds (x,y) s.t.
pair<int64_t, int64_t> euclid(int64_t A, int64_t B) {
    // Ax+By=gcd(A,B), |Ax|,|By|<=AB/gcd(A,B)
    if (!B) return {1, 0};
    pair<int64_t, int64_t> p = euclid(B, A%B);

ll max_X = cdiv(new_B*max_Y-C,A); // must have x <= max_X
if (max_X*A-new_B*max_Y+C >= new_B) --max_X;
// now we can remove upper bound on y
return minRemainder(A,new_B,C,max_X);
}
```

4.4 Pythagorean Triples

The Pythagorean triples are uniquely generated by

$a = k \cdot (m^2 - n^2), \quad b = k \cdot (2mn), \quad c = k \cdot (m^2 + n^2),$

with $m > n > 0, k > 0, m \perp n$, and either m or n even.

4.5 Lifting the Exponent

For $n > 0, p$ prime, and ints x, y s.t. $p \nmid x, y$ and $p | x - y$:

- $p \neq 2$ or $p = 2, 4 | x - y \implies v_p(x^n - y^n) = v_p(x - y) + v_p(n).$
- $p = 2, 2 | n \implies v_2(x^n - y^n) = v_2((x^2)^{n/2} - (y^2)^{n/2}).$

Combinatorial (5)

5.1 Permutations

5.1.1 Cycles

Let $g_S(n)$ be the number of n -permutations whose cycle lengths all belong to the set S . Then

$$\sum_{n=0}^\infty g_S(n) \frac{x^n}{n!} = \exp\left(\sum_{n \in S} \frac{x^n}{n}\right)$$

5.1.2 Burnside’s lemma

Given a group G of symmetries and a set X , the number of elements of X up to symmetry equals

$$\frac{1}{|G|} \sum_{g \in G} |X^g|,$$

where X^g are the elements fixed by g ($g.x = x$).

If $f(n)$ counts “configurations” (of some sort) of length n , we can ignore rotational symmetry using $G = \mathbb{Z}_n$ to get

$$g(n) = \frac{1}{n} \sum_{k=0}^{n-1} f(\gcd(n, k)) = \frac{1}{n} \sum_{k | n} f(k) \phi(n/k).$$

5.2 Partitions and subsets

5.2.1 Partition function

Number of ways of writing n as a sum of positive integers, disregarding the order of the summands.

$$p(0) = 1, \quad p(n) = \sum_{k \in \mathbb{Z} \setminus \{0\}} (-1)^{k+1} p(n - k(3k - 1)/2)$$

$$p(n) \sim 0.145/n \cdot \exp(2.56\sqrt{n})$$

n	0	1	2	3	4	5	6	7	8	9	20	50	100
$p(n)$	1	1	2	3	5	7	11	15	22	30	627	$\sim 2e5$	$\sim 2e8$

5.2.2 Lucas’ Theorem

Let n, m be non-negative integers and p a prime. Write $n = n_k p^k + \dots + n_1 p + n_0$ and $m = m_k p^k + \dots + m_1 p + m_0$. Then $\binom{n}{m} \equiv \prod_{i=0}^k \binom{n_i}{m_i} \pmod{p}$.

5.3 General purpose numbers

5.3.1 Bernoulli numbers

EGF of Bernoulli numbers is $B(t) = \frac{t}{e^t - 1}$ (FFT-able).

$$B[0, \dots] = [1, -\frac{1}{2}, \frac{1}{6}, 0, -\frac{1}{30}, 0, \frac{1}{42}, \dots]$$

Sums of powers:

$$\sum_{i=1}^n i^m = \frac{1}{m+1} \sum_{k=0}^m \binom{m+1}{k} B_k (n+1)^{m+1-k}$$

Euler-Maclaurin formula for infinite sums:

$$\sum_{i=m}^\infty f(i) = \int_m^\infty f(x) dx - \sum_{k=1}^\infty \frac{B_k}{k!} f^{(k-1)}(m)$$
$$\approx \int_m^\infty f(x) dx + \frac{f(m)}{2} - \frac{f'(m)}{12} + \frac{f'''(m)}{720} + O(f^{(5)}(m))$$

5.3.2 Stirling numbers of the first kind

Number of permutations on n items with k cycles.

$$c(n, k) = c(n - 1, k - 1) + (n - 1)c(n - 1, k), \quad c(0, 0) = 1$$
$$\sum_{k=0}^n c(n, k) x^k = x(x + 1) \dots (x + n - 1)$$

$$c(8, k) = 8, 0, 5040, 13068, 13132, 6769, 1960, 322, 28, 1$$
$$c(n, 2) = 0, 0, 1, 3, 11, 50, 274, 1764, 13068, 109584, \dots$$

5.3.3 Eulerian numbers

Number of permutations $\pi \in S_n$ in which exactly k elements are greater than the previous element. k j :s s.t. $\pi(j) > \pi(j + 1)$, $k + 1$ j :s s.t. $\pi(j) \geq j$, k j :s s.t. $\pi(j) > j$.

$$E(n, k) = (n - k)E(n - 1, k - 1) + (k + 1)E(n - 1, k)$$

$$E(n, 0) = E(n, n - 1) = 1$$

$$E(n, k) = \sum_{j=0}^k (-1)^j \binom{n+1}{j} (k+1-j)^n$$

5.3.4 Stirling numbers of the second kind

Partitions of n distinct elements into exactly k groups.

$$S(n, k) = S(n - 1, k - 1) + kS(n - 1, k)$$

$$S(n, 1) = S(n, n) = 1$$

$$S(n, k) = \frac{1}{k!} \sum_{j=0}^k (-1)^{k-j} \binom{k}{j} j^n$$

5.3.5 Bell numbers

Total number of partitions of n distinct elements. $B(n) = 1, 1, 2, 5, 15, 52, 203, 877, 4140, 21147, \dots$ For p prime,

$$B(p^m + n) \equiv mB(n) + B(n + 1) \pmod{p}$$

5.3.6 Labeled unrooted trees

on n vertices: n^{n-2}
on k existing trees of size n_i : $n_1 n_2 \dots n_k n^{k-2}$
with degrees d_i : $(n - 2)! / ((d_1 - 1)! \dots (d_n - 1)!)$

5.3.7 Catalan numbers

$$C_n = \frac{1}{n+1} \binom{2n}{n} = \binom{2n}{n} - \binom{2n}{n+1} = \frac{(2n)!}{(n+1)!n!}$$

$$C_0 = 1, \quad C_{n+1} = \frac{2(2n+1)}{n+2} C_n, \quad C_{n+1} = \sum C_i C_{n-i}$$

$$C_n = 1, 1, 2, 5, 14, 42, 132, 429, 1430, 4862, 16796, 58786, \dots$$

- sub-diagonal monotone paths in an $n \times n$ grid.
- strings with n pairs of parenthesis, correctly nested.
- binary trees with $n + 1$ leaves (0 or 2 children).
- ordered trees with $n + 1$ vertices.
- ways a convex polygon with $n + 2$ sides can be cut into triangles by connecting vertices with straight lines.
- permutations of $[n]$ with no 3-term increasing subseq.

5.4 Young Tableaux

Let a **Young diagram** have shape $\lambda = (\lambda_1 \geq \dots \geq \lambda_k)$, where λ_i equals the number of cells in the i -th (left-justified) row from the top. A **Young tableau** of shape λ is a filling of the $n = \sum \lambda_i$ cells with a permutation of $1 \dots n$ such that each row and column is increasing.

Hook-Length Formula: For the cell in position (i, j) , let $h_\lambda(i, j) = |\{(I, J) | i \leq I, j \leq J, (I = i \text{ or } J = j)\}|$. The number of Young tableaux of shape λ is equal to $f^\lambda = \frac{n!}{\prod h_\lambda(i, j)}$.

Schensted’s Algorithm: converts a permutation σ of length n into a pair of Young Tableaux $(S(\sigma), T(\sigma))$ of the same shape. When inserting $x = \sigma_i$,

1. Add x to the first row of S by inserting x in place of the largest y with $x < y$. If y doesn’t exist, push x to the end of the row, set the value of T at that position to be i , and stop.
2. Add y to the second row using the same rule, keep repeating as necessary.

All pairs $(S(\sigma), T(\sigma))$ of the same shape correspond to a unique σ , so $n! = \sum (f^\lambda)^2$. Also, $S(\sigma^R) = S(\sigma)^T$.

Let $d_k(\sigma), a_k(\sigma)$ be the lengths of the longest subseqs which are a union of k decreasing/ascending subseqs, respectively. Then $a_k(\sigma) = \sum_{i=1}^k \lambda_i, d_k(\sigma) = \sum_{i=1}^k \lambda_i^*$, where λ_i^* is size of the i -th column.

5.5 Other

DeBruijnSequence.h

Description: Given alphabet $[0, k)$ constructs a cyclic string of length k^n that contains every length n string as substring.

```
dfecad, 14 lines
vector<int> deBruijnSequence(int k, int n) {
    if (k == 1) return {0};
    vector<int> seq, aux(n+1);
    auto gen = [&](this auto&& self, int t, int p)->void {
        if (t > n && n%p == 0) for (int i = 1; i <= p; i++) {
            seq.push_back(aux[i]);
        }
        else if (t <= n) {
            aux[t] = aux[t-p]; self(t+1, p);
            while (++aux[t] < k) self(t+1, t);
        }
    };
    gen(1, 1); return seq;
}
```

NimProduct.h

Description: Product of nimbers is associative, commutative, and distributive over addition (xor). Forms finite field of size 2^{2^k} . Defined by $ab = \text{mex}(\{a'b + ab' + a'b' : a' < a, b' < b\})$. Application: Given 1D coin turning games G_1, G_2 $G_1 \times G_2$ is the 2D coin turning game defined as follows. If turning coins at $x_1, x_2, \dots, x_m$ is legal in G_1 and $y_1, y_2, \dots, y_n$ is legal in G_2 , then turning coins at all positions (x_i, y_j) is legal assuming that the coin at (x_m, y_n) goes from heads to tails. Then the Grundy function $g(x, y)$ of $G_1 \times G_2$ is $g_1(x) \times g_2(y)$.

Time: 64^2 xors per multiplication, memorize to speed up.

}
```

MatrixInv.h

Description: Uses gaussian elimination to convert into reduced row echelon form and calculates determinant. For determinant via arbitrary modulus, use a modified form of the Euclidean algorithm because modular inverse may not exist. If you have computed $A^{-1} \pmod{p^k}$, then the inverse $\pmod{p^{2k}}$ is $A^{-1}(2I - AA^{-1})$.

Time: $\mathcal{O}(N^3)$, determinant of 1000×1000 matrix of modints in 1 second if you reduce # of operations by half

PolyInvSimpler.h
Description: computes A^{-1} such that $AA^{-1} \equiv 1 \pmod{x^n}$. Newton's method: If you want $F(x) = 0$ and $F(Q_k) \equiv 0 \pmod{x^a}$ then $Q_{k+1} = Q_k - \frac{F(Q_k)}{F'(Q_k)} \pmod{x^{2a}}$ satisfies $F(Q_{k+1}) \equiv 0 \pmod{x^{2a}}$. Application: if $f(n), g(n)$ are the #s of forests and trees on n nodes then $\sum_{n=0}^{\infty} f(n)x^n = \exp\left(\sum_{n=1}^{\infty} \frac{g(n)}{n!}\right)$.

Usage: vmi v{1,5,2,3,4}; ps(exp(2*log(v,9),9)); // squares v
Time: $\mathcal{O}(N \log N)$. For $N = 5 \cdot 10^5$, inv~270ms, log ~350ms, exp~550ms

}
template<class F> db quad(F f, db a, db b, db eps = 1e-8) {
    return rec(f,a,b,eps,simpson(f,a,b)); }
```

Simplex.h

Description: Solves a general linear maximization problem: maximize $c^T x$ subject to $Ax \leq b$, $x \geq 0$. Returns -inf if there is no solution, inf if there are arbitrarily good solutions, or the maximum value of $c^T x$ otherwise. The input vector is set to an optimal x (or in the unbounded case, an arbitrary solution fulfilling the constraints). Numerical stability is not guaranteed. For better performance, define variables such that $x = 0$ is viable.
Usage: vvd A{{1,-1}, {-1,1}, {-1,-2}};
vvd b{1,1,-4}, c{-1,-1}, x;
T val = LPSolver(A, b, c).solve(x);
Time: $\mathcal{O}(NM \cdot \#pivots)$, where a pivot may be e.g. an edge relaxation.
 $\mathcal{O}(2^N)$ in the general case.

```
using T = db; // double probably suffices
using vd = V<T>; using vvd = V<vd>;

};
```

Graphs (7)

Erdos-Gallai: $d_1 \geq \dots \geq d_n$ can be degree sequence of simple graph on n vertices iff their sum is even and $\sum_{i=1}^k d_i \leq k(k-1) + \sum_{i=k+1}^n \min(d_i, k), \forall 1 \leq k \leq n$.

7.1 Basics

DirectedCycle.h

Description: stack c746ee, 28 lines

```
struct DirectedCycle {
    int N;
    vector<bool> inStk, vis;
    vector<int> stk, cyc;
    vector<vector<int>> adj;
    DirectedCycle(int _N) {
        N = _N;
        adj.resize(N);
        inStk.resize(N), vis.resize(N);
    }
    void ae(int u, int v) { adj[u].push_back(v); }
```

```
vector<int> gen() {
    for (int u = 0; u < N; u++) {
        if (!vis[u] && empty(cyc)) dfs(u);
    }
    return cyc;
}
void dfs(int u) {
    stk.push_back(u);
    inStk[u] = vis[u] = 1;
    for (auto& v: adj[u]) {
        if (inStk[v]) cyc = {ranges::find(stk, v), end(stk)};
        else if (!vis[v]) dfs(v);
        if (size(cyc)) return;
    }
    stk.pop_back(); inStk[u] = 0;
}
};
```

GridBFS.h
Description: BFS through grid with fixed xdir and ydir arrays

```
const int dx[4] = {1, 0, -1, 0};
const int dy[4] = {0, 1, 0, -1};

bool valid(int x, int y) {
    return !(x < 0 || x >= n || y < 0 || y >= m);
}

void bfs(pair<int, int> src) {
    dist[src.first][src.second] = 0;
    queue<pair<int, int>> todo; todo.push(src);
    while (!todo.empty()) {
        auto [uX, uY] = todo.front(); todo.pop();
        for (int i = 0; i < 4; i++) {
            int vX = uX+dx[i], vY = uY+dy[i];
            if (!valid(vX, vY) || dist[vX][vY] != -1) continue;
            dist[vX][vY] = dist[uX][uY]+1;
            todo.push({vX, vY});
        }
    }
}
```

Bipartite.h
Description: Checks if an undirected graph is bipartite. Colors nodes with 1/2. If not bipartite, returns false.
Time: $\mathcal{O}(N + M)$

```
struct Bipartite {
    int N;
    vector<int> color;
    vector<vector<int>> adj;
    Bipartite(int _N) {

    }
};

```

7.2.1 SqrtDecompton

HLD generally suffices. If not, here are some common strategies:

- Rebuild the tree after every $\sqrt{N}$ queries.
- Consider vertices with $>$ or $< \sqrt{N}$ degree separately.
- For subtree updates, note that there are $\mathcal{O}(\sqrt{N})$ distinct sizes among child subtrees of any node.

Block Tree: Use a DFS to split edges into contiguous groups of size $\sqrt{N}$ to $2\sqrt{N}$.

Mo’s Algorithm for Tree Paths: Maintain an array of vertices where each one appears twice, once when a DFS enters the vertex (st) and one when the DFS exists (en). For a tree path $u \leftrightarrow v$ such that $st[u] < st[v]$,

- If u is an ancestor of v , query $[st[u], st[v]]$.
- Otherwise, query $[en[u], st[v]]$ and consider $LCA(u,v)$ separately.

Solutions with worse complexities can be faster if you optimize the operations that are performed most frequently. Use arrays instead of vectors whenever possible. Iterating over an array in order is faster than iterating through the same array in some other order (ex. one given by a random permutation) or DFSing on a tree of the same size. Also, the difference between $\sqrt{N}$ and the optimal block (or buffer) size can be quite large. Try up to 5x smaller or larger (at least).

7.3 DFS Algorithms

EulerPath.h

Description: Eulerian path starting at src if it exists, visits all edges exactly once. Works for both directed and undirected. Returns vector of {vertex,label of edge to vertex}. Second element of first pair is always -1.
Time: $\mathcal{O}(N + M)$

```
9c222d, 23 lines
template<bool directed> struct Euler {

};
```

7.5 Flows

Konig's Theorem: In a bipartite graph, max matching = min vertex cover.

Dilworth's Theorem: For any partially ordered set, the sizes of the max antichain and of the min chain decomposition are equal. Equivalent to Konig's theorem on the bipartite graph (U, V, E) where $U = V = S$ and (u, v) is an edge when $u < v$. Those vertices outside the min vertex cover in both U and V form a max antichain.

Dinic.h
Description: Fast flow. After computing flow, edges $\{u, v\}$ such that $lev[u] \neq -1, lev[v] = -1$ are part of min cut. Use reset and rcap for Gomory-Hu.
Time: $\mathcal{O}(N^2M)$ flow, $\mathcal{O}\left(M\sqrt{N}\right)$ bipartite matching b7b370, 38 lines

```

f(mid) ? hi = mid : lo = mid + 1;
}
return lo;
};

```

lstTrue.h

Description: Finds the last value x in $[lo, hi]$ such that predicate $f(x)$ is true.

Usage: `int ans = fstTrue()`

Time: $\mathcal{O}(\log(hi - lo))$

8aff85, 9 lines

```

template<typename T, typename U> T lstTrue(T lo, T hi, U f) {
--lo;
assert(lo <= hi);
while (lo < hi) {
T mid = lo + (hi - lo + 1) / 2;
f(mid) ? lo = mid : hi = mid - 1;
}
return lo;
};

```

realTrue.h

Description: Binary search on continuous (floating-point) domain.

Usage: `int ans = realTrue()`

Time: $\mathcal{O}(\log(\text{precision}))$ — write 100 iterations and have a relax

691e1d, 7 lines

```

template<typename T, typename U> T realTrue(T lo, T hi, U f) {
for (int i = 0; i < 100; ++i) {
T mid = 0.5 * (hi + lo);
f(mid) ? lo = mid : hi = mid;
}
return lo;
}

```

};

Ternary.h

Description: Ternary search to find the min of a unimodal function

Time: $\mathcal{O}(\log(N/\epsilon))$

ef144f, 9 lines

```

template<typename U>
double Ternary(double lo, double hi, U f) {
while (hi - lo > eps) {
double l = lo + (hi - lo) / 3;
double r = hi - (hi - lo) / 3;
f(l) > f(r) ? lo = l : hi = r;
}
return lo;
}

```

10.2 Dynamic programming

When doing DP on intervals:

$a[i][j] = \min_{i < k < j} (a[i][k] + a[k][j]) + f(i, j)$, where the (minimal) optimal k increases with both i and j ,

- one can solve intervals in increasing order of length, and search $k = p[i][j]$ for $a[i][j]$ only between $p[i][j-1]$ and $p[i+1][j]$.

- This is known as Knuth DP. Sufficient criteria for this are if $f(b, c) \leq f(a, d)$ and $f(a, c) + f(b, d) \leq f(a, d) + f(b, c)$ for all $a \leq b \leq c \leq d$.

- Consider also: LineContainer (ch. Data structures), monotone queues, ternary search.

CircularLCS.h

Description: Used only twice. For strs A, B calculates longest common subsequence of A with all rotations of B

Time: $\mathcal{O}(|A| \cdot |B|)$

db21cf, 26 lines

```

int circular_lcs(str A, str B) {
B += B;
int max_lcs = 0;
V<vb> dif_left(sz(A)+1,vb(sz(B)+1)), dif_up(sz(A)+1,vb(sz(B)
↳+1));
auto recalc = [&](int x, int y) { assert(x && y);
int res = (A.at(x-1) == B.at(y-1)) |
dif_up[x][y-1] | dif_left[x-1][y];
dif_left[x][y] = res-dif_up[x][y-1];
dif_up[x][y] = res-dif_left[x-1][y];
};
FOR(i,1,sz(A)+1) FOR(j,1,sz(B)+1) recalc(i,j);
FOR(j,sz(B)/2) {
// 1. zero out dp[.][j], update dif_left and dif_right
if (j) for (int x = 1, y = j; x <= sz(A) && y <= sz(B); ) {
int pre_up = dif_up[x][y];
if (y == j) dif_up[x][y] = 0;
else recalc(x,y);
(pre_up == dif_up[x][y]) ? ++x : ++y;
}
// 2. calculate LCS(A[0:sz(A)), B[j:j+sz(B)/2])
int cur_lcs = 0;
FOR(x,1,sz(A)+1) cur_lcs += dif_up[x][j+sz(B)/2];
ckmax(max_lcs,cur_lcs);
}
return max_lcs;
}
}

```

SMAWK.h
Description: Given negation of totally monotone matrix with entries of type D, find indices of row maxima (their indices increase for every submatrix). If tie, take lesser index. f returns matrix entry at (r,c) in O(1). Use in place of divide & conquer to remove a log factor.
Time: $\mathcal{O}(R+C)$, can be reduced to $\mathcal{O}(C(1+\log R/C))$ evaluations of f

```
template<class F, class D=ll> vi smawk (F f, vi x, vi y) {
    vi ans(sz(x),-1); // x = rows, y = cols
    #define upd() if (ans[i] == -1 || w > mx) ans[i] = c, mx = w
    if (min(sz(x),sz(y)) <= 8) {
        FOR(i,sz(x)) { int r = x[i]; D mx;
            each(c,y) { D w = f(r,c); upd(); } }
        return ans;
    }
    if (sz(x) < sz(y)) { // reduce subset of cols to consider
        vi Y; each(c,y) {
            for (;sz(Y);Y.pop_back()) { int X = x[sz(Y)-1];
                if (f(X,Y.bk) >= f(X,c)) break; }
            if (sz(Y) < sz(x)) Y.pb(c);
        } y = Y;
    } // recurse on half the rows
    vi X; for (int i = 1; i < sz(x); i += 2) X.pb(x[i]);
    vi ANS = smawk(f,X,y); FOR(i,sz(ANS)) ans[2*i+1] = ANS[i];
    for (int i = 0, k = 0; i < sz(x); i += 2){
        int to = i+1 < sz(ans) ? ans[i+1] : y.bk; D mx;
        for(int r = x[i];;++k) {
            int c = y[k]; D w = f(r,c); upd();
            if (c == to) break; }
    }
    return ans;
};
```

10.3 Debugging tricks

- signal(SIGSEGV, [](int) { _Exit(0); }); converts segfaults into Wrong Answers. Similarly one can catch SIGABRT (assertion failures) and SIGFPE (zero divisions). _GLIBCXX_DEBUG violations generate SIGABRT (or SIGSEGV on gcc 5.4.0 apparently).
- feenableexcept(29); kills the program on NaNs (1), 0-divs (4), infinities (8) and denormals (16).

10.4 Optimization tricks

10.4.1 Bit hacks

- x & -x is the least bit in x.
- for (int x = m; x;) { --x &= m; ... } loops over all subset masks of m (except m itself).
- c = x&-x, r = x+c; ((r^x) >> 2)/c | r is the next number after x with the same number of bits set.
- FOR(b,k) FOR(i,1<=K) if (i&1<=b) D[i] += D[i^(1<=b)]; computes all sums of subsets.

10.4.2 STL Utilities

- ranges::rotate(p, ranges::min_element(p)); Lexicographically smallest cyclic shift.
- next_permutation(v.begin(), v.end()); Next permutation.

- prev_permutation(v.begin(), v.end()); Previous permutation.
- auto [mn, mx] = ranges::minmax(v); Min and max in one pass.
- ranges::nth_element(v, v.begin()+k); k-th smallest in $\mathcal{O}(n)$.
- ranges::binary_search(v, x); Check existence in sorted vector.
- ranges::lower_bound(v, x); First element $\geq x$.
- ranges::upper_bound(v, x); First element $> x$.
- int cnt = ranges::upper_bound(v, R) - ranges::lower_bound($\hookrightarrow$ v, L); Count of elements in range $[L, R]$.
- auto [l,r] = equal_range(v.begin(),v.end(),x); Range of equal values.
- v.erase(unique(v.begin(),v.end(),v.end())); Remove duplicates (after sort).
- iota(v.begin(),v.end(),0); Fill with increasing values.
- Prefix sum

```
inclusive_scan(v.begin(), v.end(), pre.begin()+1,
[](auto sum, auto x){ return sum + x; }, 0LL
);
```

10.4.3 Pragmas

- #pragma GCC optimize ("Ofast") will make GCC auto-vectorize for loops and optimizes floating points better (assumes associativity and turns off denormals).
- #pragma GCC target ("avx,avx2") can double performance of vectorized code, but causes crashes on old machines. Also consider older #pragma GCC target ("sse4").
- #pragma GCC optimize ("trapv") kills the program on integer overflows (but is really slow).

FastIO.h
Description: Fast input and output for integers and strings. For doubles, read them as strings and convert them to double using std.
Usage: initO(); int a,b; ri(a,b); wi(b,'n'); wi(a,'n');
Time: input is ~300ms faster for 10⁶ long longs on CF.

```
inline namespace FastIO {
const int BSZ = 1<<15; //INPUT
char ibuf[BSZ]; int ipos, ilen;
char nc() { // next char
    if (ipos == ilen) {
        ipos = 0; ilen = fread(ibuf,1,BSZ,stdin);
        if (!ilen) return EOF;
    }
    return ibuf[ipos++];
}
void rs(str& x) { // read str
    char ch; while (isspace(ch = nc()));
    do { x += ch; } while (!isspace(ch = nc()) && ch != EOF);
}
```

```
}
tcT> void ri(T& x) { // read int or ll
    char ch; int sgn = 1;
    while (!isdigit(ch = nc())) if (ch == '-') sgn *= -1;
    x = ch-'0'; while (isdigit(ch = nc())) x = x*10+(ch-'0');
    x *= sgn;
}
tcT, class... Ts> void ri(T& t, Ts&... ts) {
    ri(t); ri(ts...); } // read ints
///// OUTPUT (call initO() at start)
char obuf[BSZ], numBuf[100]; int opos;
void flushOut() { fwrite(obuf,1,opos,stdout); opos = 0; }
void wc(char c) { // write char
    if (opos == BSZ) flushOut();
    obuf[opos++] = c; }
void ws(str s) { each(c,s) wc(c); } // write str
tcT> void wi(T x, char after = '\0') {
    if (x < 0) wc('-'), x *= -1;
    int len = 0; for (;x>=10;x/=10) numBuf[len++] = '0'+(x%10);
    wc('0'+x); R0F(i,len) wc(numBuf[i]);
    if (after) wc(after);
}
void initO() { assert(atexit(flushOut) == 0); }
}
```

10.5 Other languages

Python3.py
Description: Python review.

```
from math import *
import sys, random
def nextInt():
    return int(input())
def nextStrs():
    return input().split()
def nextInts():
    return list(map(int,nextStrs()))

n = nextInt()
v = [n]
def process(x):
    global v
    x = abs(x)
    V = []
    for t in v:
        g = gcd(t,x)
        if g != 1:
            V.append(g)
        if g != t:
            V.append(t//g)
    v = V

    x = random.randint(0,n-1)
    if gcd(x,n) != 1:
        process(x)
    else:
        sx = x*x%n # assert(gcd(sx,n) == 1)
        print(f"sqrt {sx}")
        sys.stdout.flush()
        X = nextInt()
        process(x+X)
        process(x-X)
print(f'! {len(v)}',end='')
for i in v:
    print(f' {i}',end='')
print()
sys.stdout.flush() # sys.exit(0) -> exit
# sys.setrecursionlimit(int(1e9)) -> stack size
```

```
# print(f'{ans:={}}') -> print ans to 6 decimal places
```

Decimal.py

Description: Arbitrary-precision decimals

5 lines

```
from decimal import *

getcontext().prec = 100 # how many digits of precision
print(Decimal(1) / Decimal(7)) # 0.142857142857...
print(Decimal(10) ** -100) # 1E-100
```

10.6 Miscellaneous

GridDirection.h

Description: Predefined direction for grid-based problems. Includes common movement sets for 2D and 3D grids such as 4-directional, 8-directional, diagonal-only, knight moves, 3D etc.

efed5e, 22 lines

```
